

At the end of the class you should be able to:

- explain how cycle checking and multiple-path pruning can improve efficiency of search algorithms
- explain the complexity of cycle checking and multiple-path pruning for different search algorithms
- justify why the monotone restriction is useful for  $A^*$  search
- predict whether forward, backward, bidirectional or island-driven search is better for a particular problem
- demonstrate how dynamic programming works for a particular problem

# Summary of Search Strategies

Strategy	Frontier Selection	Complete	Halts	Space
Depth-first	Last node added			
Breadth-first	First node added			
Heuristic depth-first	Local min $h(p)$			
Best-first	Global min $h(p)$			
Lowest-cost-first	Minimal $cost(p)$			
$A^*$	Minimal $f(p)$			

**Complete** — if there a path to a goal, it can find one, even on infinite graphs.

**Halts** — on finite graph (perhaps with cycles).

**Space** — as a function of the length of current path

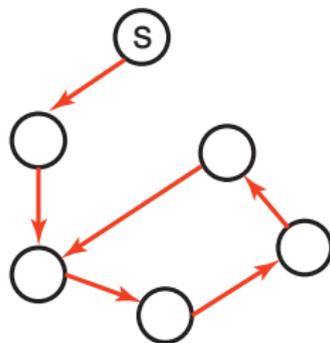

# Summary of Search Strategies

Strategy	Frontier Selection	Complete	Halts	Space
Depth-first	Last node added	No	No	Linear
Breadth-first	First node added	Yes	No	Exp
Heuristic depth-first	Local min $h(p)$	No	No	Linear
Best-first	Global min $h(p)$	No	No	Exp
Lowest-cost-first	Minimal $cost(p)$	Yes	No	Exp
$A^*$	Minimal $f(p)$	Yes	No	Exp

**Complete** — if there a path to a goal, it can find one, even on infinite graphs.

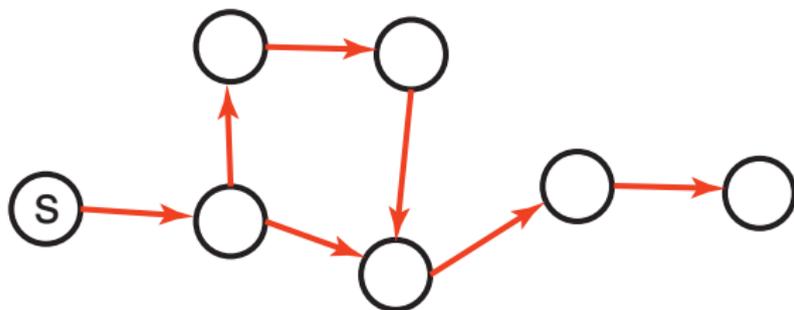

**Halts** — on finite graph (perhaps with cycles).

**Space** — as a function of the length of current path

- A searcher can prune a path that ends in a node already on the path, without removing an optimal solution.
- In depth-first methods, checking for cycles can be done in \_\_\_\_\_ time in path length.
- For other methods, checking for cycles can be done in \_\_\_\_\_ time in path length.
- Does cycle checking mean the algorithms halt on finite graphs?

# Multiple-Path Pruning

- Multiple path pruning: prune a path to node  $n$  that the searcher has already found a path to.
- What needs to be stored?
- How does multiple-path pruning compare to cycle checking?
- Do search algorithms with multiple-path pruning always halt on finite graphs?
- What is the space & time overhead of multiple-path pruning?
- Can multiple-path pruning prevent an optimal solution being found?

# Multiple-Path Pruning & Optimal Solutions

**Problem:** what if a subsequent path to  $n$  is shorter than the first path to  $n$ ?

**Problem:** what if a subsequent path to  $n$  is shorter than the first path to  $n$ ?

- remove all paths from the frontier that use the longer path.
- change the initial segment of the paths on the frontier to use the shorter path.
- ensure this doesn't happen. Make sure that the shortest path to a node is found first.

# Multiple-Path Pruning & $A^*$

- Suppose path  $p$  to  $n$  was selected, but there is a shorter path to  $n$ . Suppose this shorter path is via path  $p'$  on the frontier.
- Suppose path  $p'$  ends at node  $n'$ .
- $p$  was selected before  $p'$ , so:

## Multiple-Path Pruning & $A^*$

- Suppose path  $p$  to  $n$  was selected, but there is a shorter path to  $n$ . Suppose this shorter path is via path  $p'$  on the frontier.
- Suppose path  $p'$  ends at node  $n'$ .
- $p$  was selected before  $p'$ , so:  
$$\text{cost}(p) + h(n) \leq \text{cost}(p') + h(n').$$
- Suppose  $\text{cost}(n', n)$  is the actual cost of a path from  $n'$  to  $n$ . The path to  $n$  via  $p'$  is shorter than  $p$  so:

## Multiple-Path Pruning & $A^*$

- Suppose path  $p$  to  $n$  was selected, but there is a shorter path to  $n$ . Suppose this shorter path is via path  $p'$  on the frontier.
- Suppose path  $p'$  ends at node  $n'$ .
- $p$  was selected before  $p'$ , so:  
 $cost(p) + h(n) \leq cost(p') + h(n')$ .
- Suppose  $cost(n', n)$  is the actual cost of a path from  $n'$  to  $n$ . The path to  $n$  via  $p'$  is shorter than  $p$  so:  
 $cost(p') + cost(n', n) < cost(p)$ .

$$cost(n', n) <$$

## Multiple-Path Pruning & $A^*$

- Suppose path  $p$  to  $n$  was selected, but there is a shorter path to  $n$ . Suppose this shorter path is via path  $p'$  on the frontier.
- Suppose path  $p'$  ends at node  $n'$ .
- $p$  was selected before  $p'$ , so:  
 $cost(p) + h(n) \leq cost(p') + h(n')$ .
- Suppose  $cost(n', n)$  is the actual cost of a path from  $n'$  to  $n$ . The path to  $n$  via  $p'$  is shorter than  $p$  so:  
 $cost(p') + cost(n', n) < cost(p)$ .

$$cost(n', n) < cost(p) - cost(p') \leq$$

## Multiple-Path Pruning & $A^*$

- Suppose path  $p$  to  $n$  was selected, but there is a shorter path to  $n$ . Suppose this shorter path is via path  $p'$  on the frontier.
- Suppose path  $p'$  ends at node  $n'$ .
- $p$  was selected before  $p'$ , so:  
 $cost(p) + h(n) \leq cost(p') + h(n')$ .
- Suppose  $cost(n', n)$  is the actual cost of a path from  $n'$  to  $n$ . The path to  $n$  via  $p'$  is shorter than  $p$  so:  
 $cost(p') + cost(n', n) < cost(p)$ .

$$cost(n', n) < cost(p) - cost(p') \leq h(n') - h(n).$$

We can ensure this doesn't occur if  
 $|h(n') - h(n)| \leq cost(n', n)$ .

# Monotone Restriction

- Heuristic function  $h$  satisfies the **monotone restriction** if  $|h(m) - h(n)| \leq \text{cost}(m, n)$  for every arc  $\langle m, n \rangle$ .
- If  $h$  satisfies the monotone restriction,  $A^*$  with multiple path pruning always finds the shortest path to a goal.
- This is a strengthening of the admissibility criterion.

# Direction of Search

- The definition of searching is symmetric: find path from start nodes to goal node or from goal node to start nodes.
- **Forward branching factor:** number of arcs out of a node.
- **Backward branching factor:** number of arcs into a node.
- Search complexity is  $b^n$ . Should use forward search if forward branching factor is less than backward branching factor, and vice versa.
- Note: when graph is dynamically constructed, the backwards graph may not be available.

# Bidirectional Search

- Idea: search backward from the goal and forward from the start simultaneously.
- This wins as  $2b^{k/2} \ll b^k$ . This can result in an exponential saving in time and space.
- The main problem is making sure the frontiers meet.
- This is often used with one breadth-first method that builds a set of locations that can lead to the goal. In the other direction another method can be used to find a path to these interesting locations.

- **Idea:** find a set of islands between  $s$  and  $g$ .

$$s \longrightarrow i_1 \longrightarrow i_2 \longrightarrow \dots \longrightarrow i_{m-1} \longrightarrow g$$

There are  $m$  smaller problems rather than 1 big problem.

- This can win as  $mb^{k/m} \ll b^k$ .
- The problem is to identify the islands that the path must pass through. It is difficult to guarantee optimality.
- The subproblems can be solved using islands  $\implies$  **hierarchy of abstractions.**

**Idea:** for statically stored graphs, build a table of  $dist(n)$  the actual distance of the shortest path from node  $n$  to a goal. This can be built backwards from the goal:

$$dist(n) = \begin{cases} 0 & \text{if } is\_goal(n), \\ \min_{\langle n,m \rangle \in A} (|\langle n,m \rangle| + dist(m)) & \text{otherwise.} \end{cases}$$

This can be used locally to determine what to do. There are two main problems:

- It requires enough space to store the graph.
- The  $dist$  function needs to be recomputed for each goal.
